investigates the problem of reputation
Our focus is on developing
a composite

one of the essential and important
use in selecting the right services
management in Web Services is
both the academic and business
of approaches

1. Why is reputation important?

2. What's so special about composite services?

3. How does one propagate reputation fairly?

Numerous services
provide similar functionalities
varying in quality

Trust

Trust in the provider's ability to meet the expectations

Trust Establishment

- rules & regulations,
- third party certificates,
- reputation

Reputation

Former consumers'
collective perception

Ebay Sellers

Recent Feedback Ratings (last 12 months) ?			
	1 month	6 months	12 months
 Positive	270	882	883
 Neutral	1	7	7
 Negative	1	2	2

Detailed Seller Ratings (last 12 months) ?		
Criteria	Average rating	Number of ratings
Item as described		661
Communication		660
Shipping time		659
Shipping and handling charges		662

Representation

detailed description,
single value,
multiple values, ...

2. What's so special about composite services?

Composition

Creation of new services by
combining existing ones

Vertical

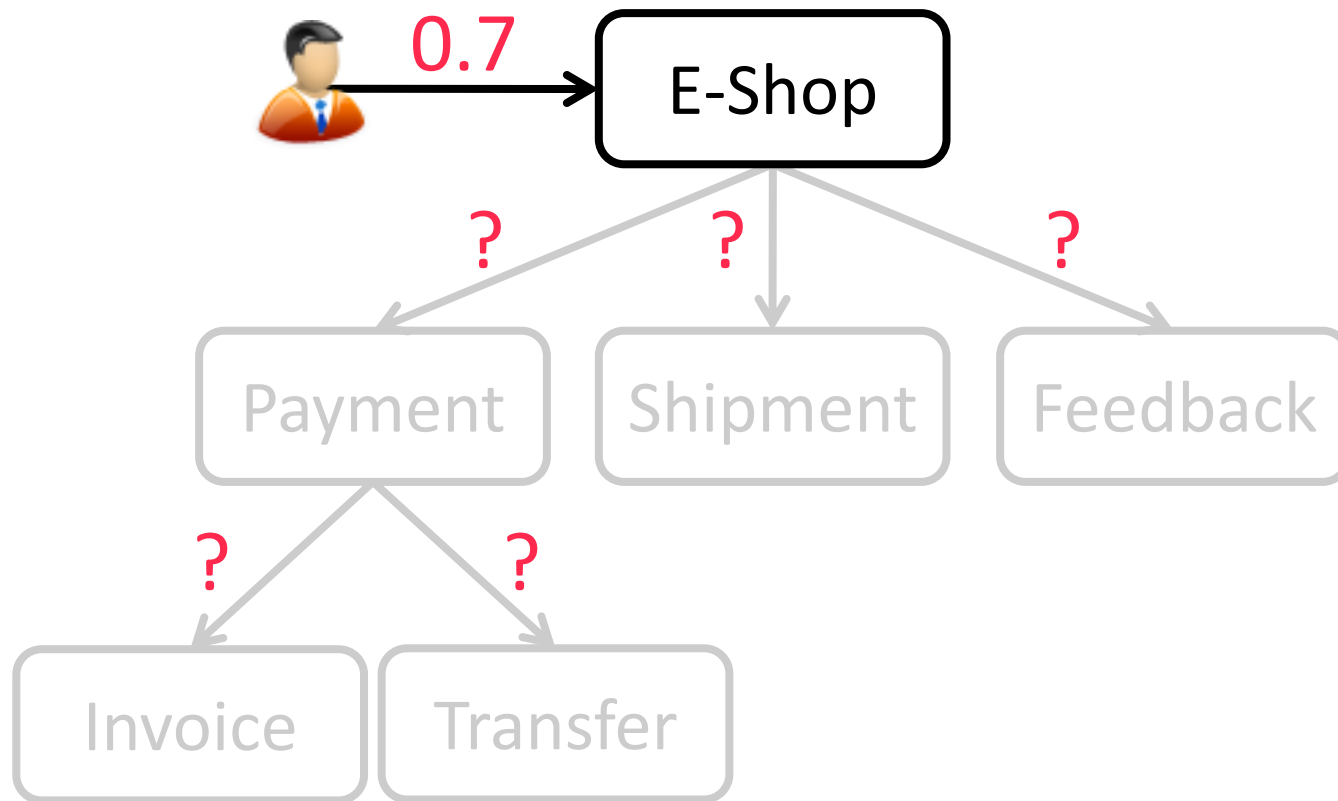

Horizontal

Hybrid

Example

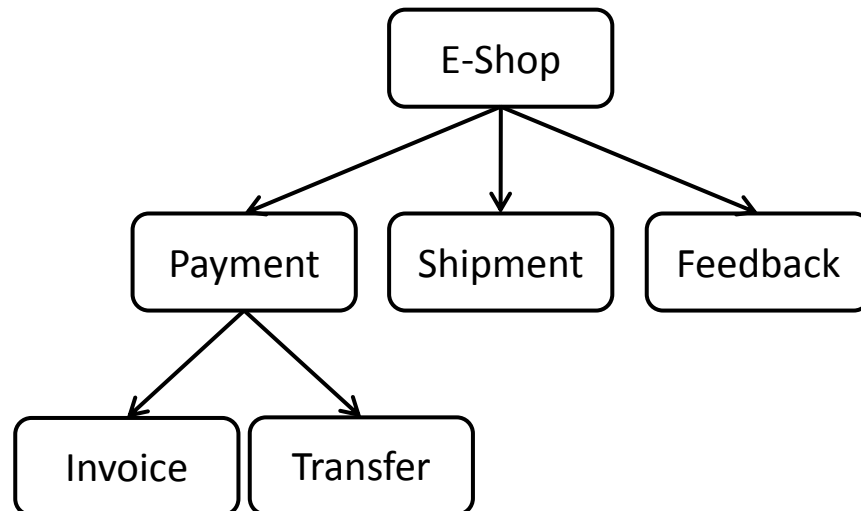

1. Different levels of contribution

2. No penalty for the poor performances of others

3. No reward for the good performances of others

4. Level of composition

Fairness

Respect all four criteria

3. How does one propagate reputation fairly?

Contribution based on
the **past behaviour**

Assumption

high reputation

high contribution

Propagation

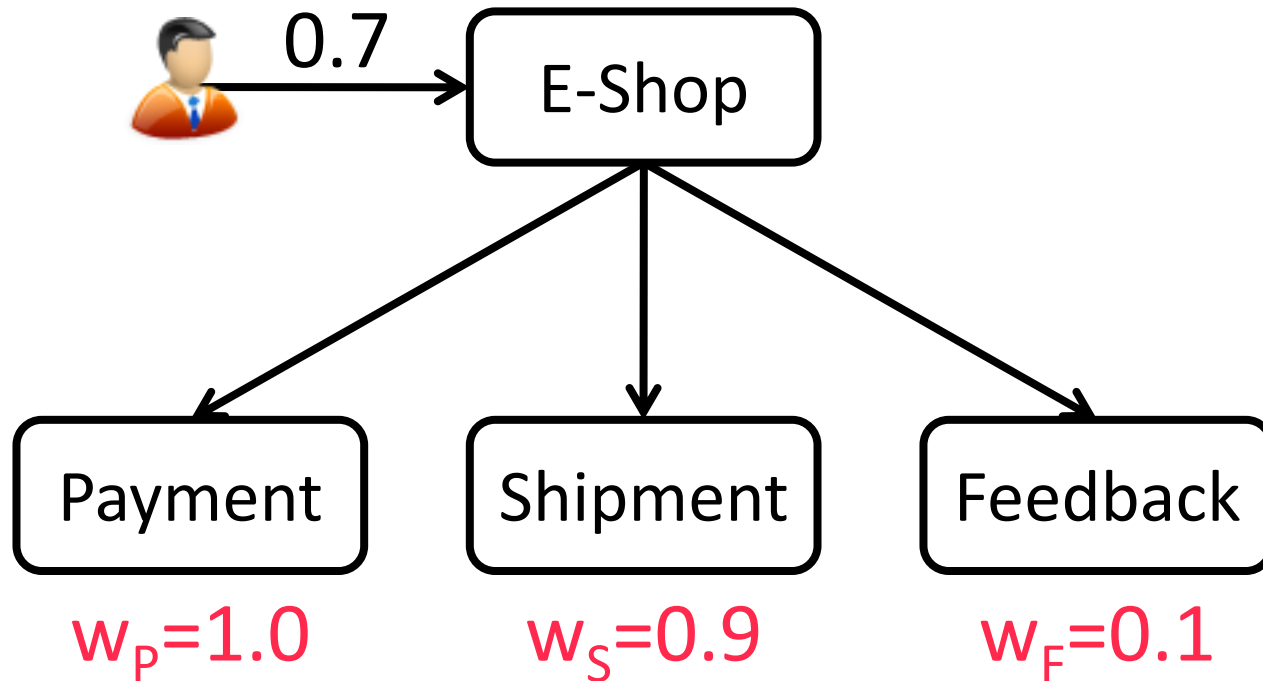

- c a composite service
- v_c an assigned reputation value
- S a set of n component services

Assignment of weights:

$$w_c = (w_{s_1}, w_{s_2}, \dots, w_{s_n})$$

$$s_i \in S \quad w_{s_i} \in [0, 1]$$

Example

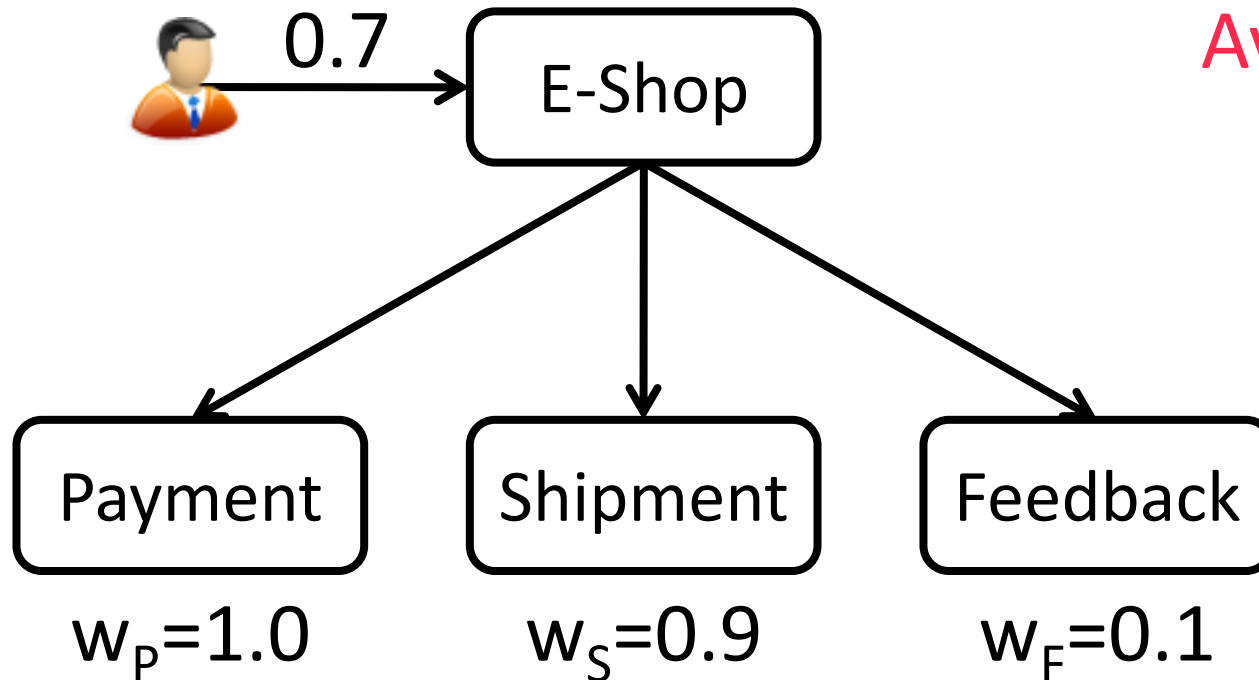

Reputation of a single service s
over a period of time k :

$$r_k^{(s,c)} \in [0, 1]$$

Average reputation:

$$r_k^{(S,c)} = \frac{\sum_{s \in S} r_k^{(s,c)}}{n}$$

Example

Avg = 0.75
P = 0.85
S = 0.70
F = 0.70

Rate of change:

$$\Delta r_k^{(s,c)} = \frac{r_k^{(s,c)} - r_k^{(S,c)}}{r_k^{(S,c)}}$$

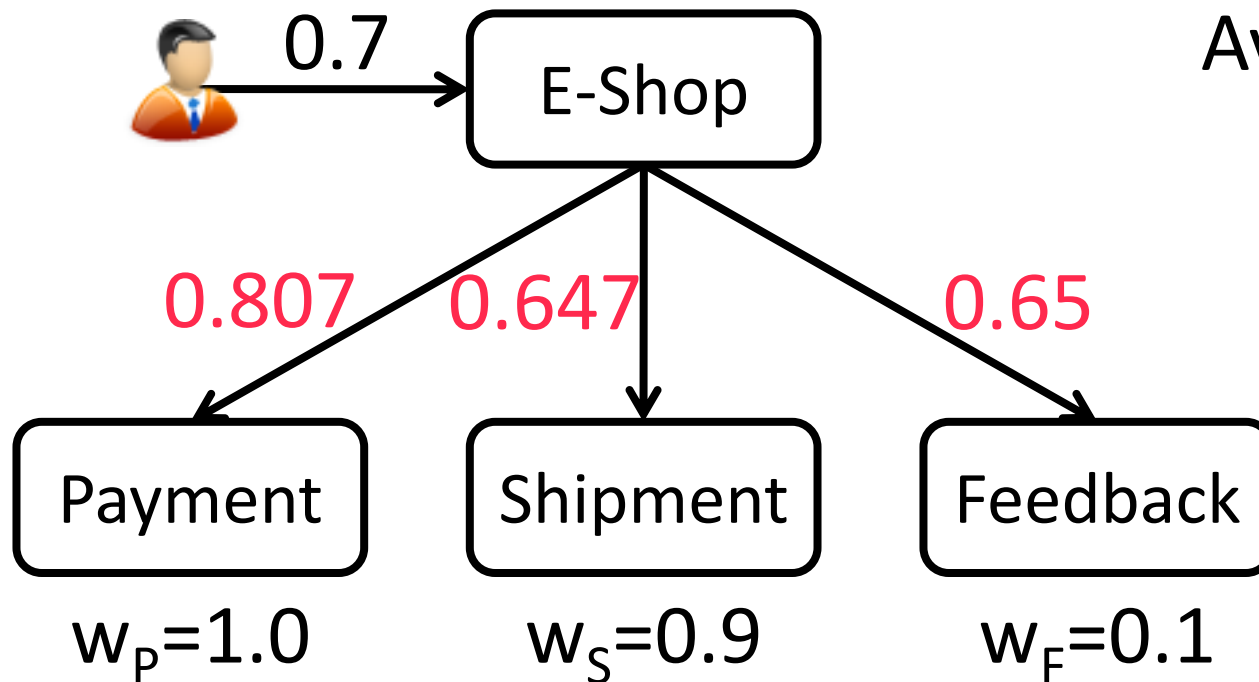

Difference new vs. average:

$$\Delta v = v_c - r_k^{(S,c)}$$

Propagated value:

$$v_s = r_k^{(s,c)} + w_s \cdot \Delta r_k^{(s,c)} \cdot |\Delta v| + \Delta v$$

Example

Avg = 0.75
P = 0.85
S = 0.70
F = 0.70

Evaluation & Discussion

Evaluation

Evaluation

Discussion

reputation concept,
underlying assumptions,
records of past behaviour, ...
